

# 1. Ideation Phase

---

*Project Title: Script-Controlled ACL - Restrict Record Access Based on Field Value*

## 1. Problem Identification & Empathy Mapping

---

In ServiceNow enterprise applications, standard Role-Based Access Control (RBAC) grants table-wide access. For example, a user with access to the `Institution Details` table can view all records across all academic branches (ECE, EEE, CSE). This creates privacy violations where sensitive student records belonging to one department are visible to members of another department.

### Empathy Map

| Category | Details                                                                                               |
|----------|-------------------------------------------------------------------------------------------------------|
| Says     | "I only want EEE department staff and students to view EEE branch records."                           |
| Thinks   | Static roles are not enough. We need dynamic evaluation based on the Branch field value.              |
| Does     | Configures script-controlled ACL rules evaluating <code>current.u_branch</code> and user roles (bb1). |
| Feels    | Concerned about unauthorized data exposure across academic branches.                                  |

## 2. Brainstorming & Solution Pitch

---

**Selected Solution:** Script-Controlled ACL (Read/Create/Write/Delete) combining custom roles (bb1, bb2, bb3, bb4), field choice values (`Branch == EEE`), and server-side GlideScript evaluation (`gs.hasRole('admin')`, `gs.hasRole('bb1')`).
